- For all questions, show your work!
- Use LaTeX and the template we provide when writing your answers. You may reuse most of the notation shorthands, equations and/or tables. See the assignment policy on the course website for more details.
- Submit your answers electronically via Gradescope.
- TAs for this assignment are Arian Khorasani and Nanda Harishankar Krishna.

Question 1 (2-5-5-5-3). (Backpropagation in RNNs)

Consider the following RNN:

$$egin{aligned} oldsymbol{h}_t &= \sigma(oldsymbol{W}oldsymbol{x}_t + oldsymbol{U}oldsymbol{h}_{t-1}) \ oldsymbol{y}_t &= oldsymbol{V}oldsymbol{h}_t \end{aligned}$$

where σ denotes the logistic sigmoid function. Let z_t be the true target of the prediction y_t and consider the sum of squared loss $L = \sum_t L_t$ where $L_t = ||z_t - y_t||_2^2$.

In this question our goal is to obtain an expression for the gradients $\nabla_{\mathbf{W}}L$ and $\nabla_{\mathbf{U}}L$.

1. First, complete the following computational graph for this RNN, unrolled for 3 time steps (from t = 1 to t = 3). Label each node with the corresponding hidden unit and each edge with the corresponding weight.

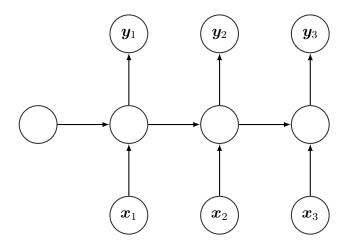

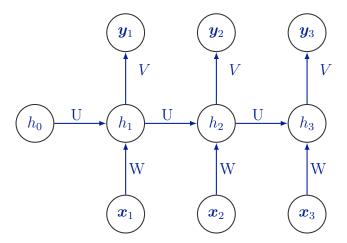

FIGURE 1 – Computational graph of the RNN unrolled for three timesteps.

2. Derive a recursive expression for the total gradient $\nabla_{h_t} L$ in terms of $\nabla_{h_t} L_t$ and $\nabla_{h_{t+1}} L$.

- 3. Derive an expression for $\nabla_{h_t} L_t$ and $\frac{\partial h_{t+1}}{\partial h_t}$.
- 4. Now derive $\nabla_{\boldsymbol{W}}L$ and $\nabla_{\boldsymbol{U}}L$ as functions of $\nabla_{\boldsymbol{h}_t}L$, using the results from the previous 2 subquestions.
 - Hint: It might be useful to consider the contribution of the weight matrices when computing the recurrent hidden unit at a particular time t and how those contributions might be aggregated.
- 5. To avoid the problem of exploding or vanishing gradients, we can use Truncated BPTT to compute gradients for parameter updates in RNNs. What can you say about the gradient estimates from Truncated BPTT are they unbiased or biased? Why do you think so? While Truncated BPTT can help mitigate exploding or vanishing gradients, what problems do you foresee with this approach, for example, in tasks involving language?

Answer 1. Guillaume Thibault

1. Labeled node with the corresponding hidden unit and edge with the corresponding weight

2. Starting the recursion from the last layer We know that

$$\frac{\partial L}{\partial L^{(t)}} = 1$$

Then, for the derivation of the loss at w.r.t. y

$$(\nabla_{y^t} L)_i = \frac{\partial L}{\partial y_i^{(t)}} = \frac{\partial L}{\partial L^{(t)}} * \frac{\partial L^{(t)}}{\partial y_i^{(t)}} = 2\sum_i (z^t - y_i^t)$$

If we look at the last layer ϕ

$$\nabla_{h^{\phi}} L = V^T \nabla_{y^{\phi}} L$$

At the previous layer $\phi - 1 = t$

$$\begin{split} \nabla_{h^t} L &= (\frac{\partial h^{(t+1)}}{\partial h^{(t)}})^T (\nabla_{h^{(t+1)}} L) + (\frac{\partial y^{(t)}}{\partial h^{(t)}}) (\nabla_{y^{(t)}} L) \\ &= W^T \mathrm{diag} (1 - (h^{(t+1)})^2) \nabla_{h^{(t+1)}} L + V^T \nabla_{y^{(t)}} L \end{split}$$

Prof: Aishwarya Agrawal

3. Derive an expression for $\nabla_{\mathbf{h}_t} L_t$ and $\frac{\partial \mathbf{h}_{t+1}}{\partial \mathbf{h}_t}$. For $\nabla_{\mathbf{h}_t} L_t$

$$\nabla_{\mathbf{h}_t} L_t = \frac{\partial L}{\partial h^{(t)}} \sum_{t} (z - V h^{(t)})^2$$
$$= 2V \sum_{t} (z - V h^{(t)})$$

For $\frac{\partial \boldsymbol{h}_{t+1}}{\partial \boldsymbol{h}_t}$

$$\frac{\partial \boldsymbol{h}_{t+1}}{\partial \boldsymbol{h}_{t}} = \frac{\partial}{\partial h^{(t)}} \sigma(Wx^{(t+1)} + Uh^{(t)})$$
$$= \sigma'(Wx^{(t+1)} + Uh^{(t)})U$$

4. Now derive $\nabla_{\boldsymbol{W}}L$ and $\nabla_{\boldsymbol{U}}L$ as functions of $\nabla_{\boldsymbol{h}_t}L$, using the results from the previous 2 subquestions

Let use the gradient of the internal node,

$$\nabla_{h^{(t)}}L = (\frac{\partial h^{(t+1)}}{\partial h^{(t)}})^T (\nabla_{h^{(t+1)}}L) + (\frac{\partial y^{(t)}}{\partial h^{(t)}})^T (y^{(t)}L)$$

and derive one step further to the weights. For that, let introduce $W^{(t)}$, a copy of W use only at time t and $U^{(t)}$, a copy of U use only at time t.

For one node:

$$\frac{\partial h}{\partial W} = \frac{\partial}{\partial W} \sigma'(Wx^{(t)} + Uh^{(t-1)})x^{(t)}$$
$$\frac{\partial h}{\partial U} = \frac{\partial}{\partial U} \sigma'(Wx^{(t)} + Uh^{(t-1)})h^{(t-1)}$$

Then we can sum all the derivative of W and U (Where i is for each layer and j is for each derivative of this layer)

$$\nabla_W L = \sum_t \sum_i \frac{\partial L}{\partial h_i^{(t)}} \nabla_W^{(t)} h_i^{(t)}$$

$$= \sum_t \sum_i \frac{\partial L}{\partial h_i^{(t)}} \sigma' (W x^{(t)} + U h^{(t-1)}) x^{(t)}$$

$$\nabla_U L = \sum_t \sum_i \frac{\partial L}{\partial h_i^{(t)}} \nabla_w^{(t)} h_i^{(t)}$$

$$= \sum_t \sum_i \frac{\partial L}{\partial h_i^{(t)}} \sigma' (W x^{(t)} + U h^{(t-1)}) h^{(t-1)}$$

5. This type of approach will favor short time dependency and link from far in the sequence will have a difficult way to propagate since we compute gradients based on only k previous steps.

RNNs, Transformers, Optimization, Regularization

Question 2 (5-5-3-5-2). (Transformers as GNNs)

Learning representations of inputs is the bedrock of all neural networks. In recent years, Transformer models have been widely adapted to sequence modeling tasks in the vision and language domains, while Graph Neural Networks (GNNs) have been effective in constructing representations of nodes and edges in graph data. In the following questions we will explore both Transformers and GNNs, and draw some connections between them.

Background:

Let us first take a look at a graph model. We define a directed graph $G = \{V, E\}$ where V is the set of all vertices and E is the set of all edges. For $\forall v_i \in V$, let us define $\mathcal{N}(v_i)$ as the set of all of v_i 's neighbors with outgoing edges towards v_i . v_i has a state representation h_i^t at each time step t.

The values of h_i^t are updated in parallel, using the same snapshot of the graph at a given time step. The procedures are as follows: We first need to aggregate the incoming data $H'_{it} = \{f_{ji}(h_j^t) | \forall j, v_j \in \mathcal{N}(v_i)\}$ from neighbors using the function $Agg(H'_{it})$. Note that the incoming data from each neighbor is a transformed version of its representation using function f_{ji} . The aggregation function $Agg(H'_{it})$ can be something like the summation or the mean of elements in H'_{it} .

Say the initial state at time step 0 is h_i^0 . Now let us define the update rule for h_i^t at time step t+1 as the following:

$$h_i^{t+1} = q(h_i^t, Agg(H_{it}')) \tag{1}$$

where q is a function $-Q_t: \{H_t, Agg(H'_t)\} \to H_t$, where $H_t = \{h_n^t | \forall n, v_n \in V\}$.

Now, let us take a look at Transformer models. Recall that Transformer models build features for each word as a function of the features of all the other words with an attention mechanism over them, while RNNs update features in a sequential fashion.

To represent a Transformer model's attention mechanism, let us define a feature representation h_i for word i in sentence S. We have the standard equation for the attention update at layer l as a function of the each other word j as follows:

$$h_i^{l+1} = \operatorname{Attention}(Q^l h_i^l, K^l h_i^l, V^l h_i^l) \tag{2}$$

$$= \sum_{j \in S} \left(\operatorname{softmax}_{j}(Q^{l} h_{i}^{l} \cdot K^{l} h_{j}^{l}) V^{l} h_{j}^{l} \right) \tag{3}$$

where Q^l, K^l, V^l are weight matrices for "Query", "Key", and "Value". Q is a matrix that contains vector representations of one word in the sentence, while K is a matrix containing representations for all the words in the sentence. V is another matrix similar to K that has representations for all words in the sentence. As a refresher for your knowledge about the Transformer model, you can refer to this paper.

Based on the above background information, answer the following questions:

RNNs, Transformers, Optimization, Regularization

- (2.1) If the aggregation operation for $Agg(H'_{it})$ is the summation of representation of all adjacent vertices, rewrite the equation 1 by replacing $Agg(H'_{it})$ in terms of \mathcal{N} , f, and h.
- (2.2) Consider the directed graph G in Fig 2. The values for the vertices at time step t are as

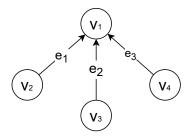

FIGURE 2 – Graph G for (2.2)

follows:

$$h_1^t = [1, -1] \quad h_2^t = [-1, 1] \quad h_3^t = [0, -1] \quad h_4^t = [1, 0]$$
 (4)

(Note: these are row vectors.)

The aggregation function $Agg(H'_{1t})$ is:

$$Agg(H'_{1t}) = [0.6, 0.2, 0.2] \begin{bmatrix} f(h_2^t) \\ f(h_3^t) \\ f(h_4^t) \end{bmatrix}$$
(5)

And the function f on all the edges is:

$$f(x) = 2x \tag{6}$$

Now, given that

$$h_1^{t+1} = q(h_1^t, Agg(H_{1t}')) = W(h_1^t)^T + max\{Agg(H_{1t}'), 0\}$$
(7)

where W = [1, 1], what is the updated value of h_1^{t+1} ?

(Note: All h_i^t and W are row vectors.)

- (2.3) Consider the graph G in question (2.2). We want to alter it to represent the sentence "I eat red apples" (4 word tokens) as a fully connected graph. Each vertex represents one word token, and the edges represent the relationships among the tokens. How many edges in all would graph G contain? Notice that the edges are directed and a bi-directional edge counts as two edges.
- (2.4) Using equations 1 and 3, show that the Transformer model's single-head attention mechanism is equivalent to a special case of a GNN.
- (2.5) An ongoing area of research in Transformer models for NLP is the challenge of learning verylong-term dependencies among entities in a sequence. Based on this connection with GNNs, why do you think this could be problematic?

Answer 2. Guillaume Thibault

1.

$$h_i^{t+1} = q(h_i^t; \sum_{v_i}^{N} f(h_{v_i}))$$

2. Given

$$h_i^{t+1} = q(h_i^t, \text{Agg}(H'_{1t})) = W(h_1^t)^T + max\{\text{Agg}(H'_{1t}), 0\}$$

The update at h_1^{t+1} is:

$$h_i^{t+1} = [1,1] \begin{bmatrix} 1 \\ -1 \end{bmatrix} + \max\{[0.6,0.2,0.2] \begin{bmatrix} f(h_2^t) \\ f(h_3^t) \\ f(h_4^t) \end{bmatrix}, 0\}$$

Where

$$\max\{[0.6, 0.2, 0.2] \begin{bmatrix} f(h_2^t) \\ f(h_3^t) \\ f(h_4^t) \end{bmatrix}, 0\} = \max\{[0.6, 0.2, 0.2] \begin{bmatrix} -2, 2 \\ 0, -2 \\ 1, 0 \end{bmatrix}, 0\}$$

$$= \max\{[-1, 0.8], 0\}$$

$$= [0, 0.8]$$

Then

$$h_i^{t+1} = [0, 0.8]$$

3. The sentence "I eat red apples" have 4 words. A fully connected bidirectional graph will then have

$$n_{word}(n_{word} - 1) = 4(4 - 1) = 12$$
edges

4. With

$$h_i^{t+1} = \sigma(Q^l h_i^L * \sum_{j \in N(i)} K^l h_j^l) V^l h_i$$

Where $Q^lK^lV^l$ are learn-able weights.

We could replace the $Agg(...) = \sum_{j \in N(i)} K^l h^l_j$ by another size-ivariant Agg(...) function.

$$Agg(H'_{ij}) = K^l h^l_i$$

$$q(h_i, Agg(H'_{ij})) = \sigma(Q^l h_i^L \circ Agg(H'_{ij})) V^l h_i$$

Then we can see the equivalence.

5. Since we saw that the transformer model's attention is a special form of GNNs. We can use our knowledge of GNNs to infer that it will be hard to have long term dependency between the data. We know that the node are only the data near a node is use for the computation there is no direct connection from far states.

Question 3 (6-2-6-6). (Optimization and Regularization)

(3.1) Batch normalization, layer normalization and instance normalization all involve calculating the mean μ and variance σ^2 with respect to different subsets of the tensor dimensions. Given the following 3D tensor, calculate the corresponding mean and variance tensors for each normalization technique: μ_{batch} , μ_{layer} , $\mu_{instance}$, σ^2_{batch} , σ^2_{layer} , and $\sigma^2_{instance}$.

$$\left[\begin{bmatrix} 4,3,2\\1,4,3 \end{bmatrix}, \begin{bmatrix} 3,4,1\\4,2,2 \end{bmatrix}, \begin{bmatrix} 3,2,3\\4,1,2 \end{bmatrix}, \begin{bmatrix} 1,1,3\\4,1,2 \end{bmatrix} \right]$$

The size of this tensor is 4 x 2 x 3 which corresponds to the batch size, number of channels, and number of features respectively.

- (3.2) While BatchNorm is very common in Computer Vision models, it is significantly outperformed by LayerNorm in Natural Language Processing tasks. What could be some problems with using BatchNorm in NLP? You may consider a naïve implementation of BatchNorm and also illustrate your point with an example if you wish.
- (3.3) Consider a linear regression problem with input data $\mathbf{X} \in \mathbb{R}^{n \times d}$, weights $\mathbf{w} \in \mathbb{R}^{d \times 1}$ and targets $\mathbf{y} \in \mathbb{R}^{n \times 1}$. Suppose that dropout is applied to the input (with probability 1 p of dropping the unit i.e. setting it to 0). Let $\mathbf{R} \in \mathbb{R}^{n \times d}$ be the dropout mask such that $\mathbf{R}_{ij} \sim \text{Bern}(p)$ is sampled i.i.d. from the Bernoulli distribution.

For a squared error loss function with dropout, we then have:

$$L(\boldsymbol{w}) = ||\boldsymbol{y} - (\boldsymbol{X} \odot \boldsymbol{R})\boldsymbol{w}||^2$$

Let Γ be a diagonal matrix with $\Gamma_{ii} = (\boldsymbol{X}^{\top}\boldsymbol{X})_{ii}^{1/2}$. Show that the expectation (over \boldsymbol{R}) of the loss function can be rewritten as $\mathbb{E}[L(\boldsymbol{w})] = ||\boldsymbol{y} - p\boldsymbol{X}\boldsymbol{w}||^2 + p(1-p)||\Gamma\boldsymbol{w}||^2$. Hint: Note we are trying to find the expectation over a squared term and use $\operatorname{Var}(Z) = \mathbb{E}[Z^2] - \mathbb{E}[Z]^2$.

(3.4) Consider a linear regression problem with a d-dimensional feature vector $\mathbf{x} \in \mathbb{R}^d$ as input and $y_i \in \mathbb{R}$ as the output. The dataset consists of n training examples $(\mathbf{x}_1, y_1), (\mathbf{x}_2, y_2), \dots, (\mathbf{x}_n, y_n)$. Let \mathbf{X} be the $n \times d$ data matrix formed by placing the feature vectors on the rows of this matrix, i.e.,

$$oldsymbol{X}^T = egin{bmatrix} oldsymbol{x}_1, oldsymbol{x}_2, \dots, oldsymbol{x}_n \end{bmatrix}$$

Let y be a column vector with elements $y_1, y_2...y_n$. We will operate in the setting where d > n, i.e., there are more feature dimensions than samples. Thus, the following linear system is under-constrained / under-determined:

$$Xw = y \tag{8}$$

> To avoid the degenerate case, we will assume that y lies in the span of X, i.e. this linear system has at least one solution.

Now, recall that the optimization problem in least-squares regression is the following:

$$\min_{\boldsymbol{w} \in \mathbf{R}^{\mathbf{d}}} \quad f(\boldsymbol{w}) = \sum_{i=1}^{n} \underbrace{(y_i - \boldsymbol{w}^T \boldsymbol{x}_i)^2}_{\text{squared error on example } i}$$
(9)

We will optimize (9) via gradient descent. Specifically, let us initialize $\mathbf{w}^{(0)} = 0$. And repeatedly take a step in the direction of negative gradient with a sufficiently-small constant step-size η till convergence:

$$\boldsymbol{w}^{(t+1)} = \boldsymbol{w}^{(t)} - \eta \nabla f(\boldsymbol{w}^{(t)})$$
(10)

Let us refer to the solution found by gradient descent at convergence as w^{gd} .

Prove that the solution found by gradient descent for least-squares is equal to the result of the following different optimization problem:

$$\mathbf{w}^{gd} = \underset{\mathbf{w} \in \mathbf{R}^{\mathbf{d}}}{\operatorname{arg \, min}} \quad ||\mathbf{w}||_{2}^{2}$$
such that $\mathbf{X}\mathbf{w} = \mathbf{y}$ (11)

such that
$$Xw = y$$
 (12)

Hint: For this optimization problem, you must work with the Lagrangian $L(\boldsymbol{w}, \lambda)$, given by

$$L(\boldsymbol{w}, \lambda) = \|\boldsymbol{w}\|^2 + \lambda^{\top} (\boldsymbol{X} \boldsymbol{w} - \boldsymbol{y})$$

Obtain \mathbf{w}^* and λ^* from the KKT conditions $(\frac{\partial L}{\partial w} = 0 \text{ and } \frac{\partial L}{\partial \lambda} = 0)$ to arrive at the result.

Answer 3. 1. Batch normalization: μ σ^2 for each individual channel across all sample and both spacial dimension.

$$\mu_c = \frac{1}{NF} \sum_{n=1}^{N} \sum_{f=1}^{F} x_{icf} = [2.5, 2.5]$$
(13)

$$\sigma_c^2 = \frac{1}{NF} \sum_{n=1}^{N} \sum_{f=1}^{F} (x_{icf} - \mu_c)^2 = [1.08, 1.42]$$
 (14)

Instance normalization: μ σ^2 for each individual channel across each individual sample across both special dimension

$$\mu_{nc} = \frac{1}{F} \sum_{f}^{F} x_{ncf} = \begin{bmatrix} 3, \frac{8}{3} \\ \frac{8}{3}, \frac{8}{3} \\ \frac{8}{3}, \frac{7}{3} \\ \frac{5}{3}, \frac{7}{3} \end{bmatrix}$$
 (15)

$$\sigma_{nc}^{2} = \frac{1}{F} \sum_{f}^{F} (x_{ncf} - \mu_{nc})^{2} = \begin{bmatrix} 0.67, 1.56 \\ 1.56, 0.89 \\ 0.22, 0.89 \\ 0.89, 1.56 \end{bmatrix}$$
(16)

Layer normalization: μ σ^2 for each individual sample across all channel and both sapcial dimension

$$\mu_n = \frac{1}{FC} \sum_{c}^{C} \sum_{f}^{F} x_{ncf} = \left[\frac{17}{6}, \frac{16}{6}, \frac{15}{6}, \frac{12}{6} \right]$$
 (17)

$$\sigma_n^2 = \frac{1}{FC} \sum_{c}^{C} \sum_{f}^{F} (x_{ncf} - \mu_n)^2 = [1.14, 1.22, 0.92, 1.33]$$
 (18)

- 2. The input sentences can have various sizes. Then the use of Batch Norm won't impact all the sentences in the same way and thus changing the meaning of the words.
- 3. Linear regression with input data $X \in \mathbb{R}^{n \times d}$, weights $\boldsymbol{w} \in \mathbb{R}^{d \times 1}$ and targets $\boldsymbol{y} \in \mathbb{R}^{n \times 1}$. The dropout is apply on the input with a probability of P(1-p). $\boldsymbol{R} \in \mathbb{R}^{n \times d}$ be the dropout mask such that $\boldsymbol{R}_{ij} \sim \text{Bern}(p)$ is sampled i.i.d. from the Bernoulli distribution.

The squared loss function with dropout is

$$L(\boldsymbol{w}) = ||\boldsymbol{y} - (\boldsymbol{X} \odot \boldsymbol{R})\boldsymbol{w}||^2$$
(19)

And Γ be a diagonal matrix with $\Gamma_{ii} = (\boldsymbol{X}^{\top} \boldsymbol{X})_{ii}^{1/2}$.

We need to show that the expectation (over \mathbf{R}) of the loss function can be rewritten as $\mathbb{E}[L(\mathbf{w})] = ||\mathbf{y} - p\mathbf{X}\mathbf{w}||^2 + p(1-p)||\Gamma\mathbf{w}||^2$.

Let's look at the problem with a matrix form

$$L(\boldsymbol{w}) = ||\boldsymbol{y} - (\boldsymbol{X} \odot \boldsymbol{R})\boldsymbol{w}||^2 = \sqrt{\sum_{i} \{y_i - (\boldsymbol{X} \odot \boldsymbol{R})_i w_i\}^2}^2$$

$$= y^T y - 2y^T (\boldsymbol{X} \odot \boldsymbol{R}) w + w^T (\boldsymbol{X} \odot \boldsymbol{R})^T (\boldsymbol{X} \odot \boldsymbol{R}) w$$
(20)

That will give us: 1xn * nx1 * 1xn * nxd * dx1 * 1xn * nxd * dxn * nx1. OK Then, taking the expectation w.r.t. R

$$\mathbb{E}_R[L(x)] = y^T y - 2y^T \mathbb{E}_R[(X \odot R)] w + w^T \mathbb{E}_R[(X \odot R)^T (X \odot R)] w$$
 (22)

Let's look at $\mathbb{E}_R[(X \odot R)]$ in detail

$$\mathbb{E}_R[(X \odot R)] = X \mathbb{E}_R[R] = \begin{bmatrix} P(p)x_1 P(p)x_2 \\ P(p)x_3 P(p)x_4 \end{bmatrix}$$
 (23)

Let explore a cell wise expected value to see it clearly

$$\begin{bmatrix} x_1, x_2 \\ x_3, x_4 \end{bmatrix} \begin{bmatrix} r_1, r_2 \\ x_3, x_4 \end{bmatrix} = \begin{bmatrix} r_1 x_1, r_2 x_2 \\ r_3 x_3, r_4 x_4 \end{bmatrix} = pX$$
 (24)

Now let's look at $\mathbb{E}_R[(X \odot R)^T(X \odot R)]$ in detail

$$\mathbb{E}_{R}[(X \odot R)^{T}(X \odot R)] = \begin{bmatrix} r_{1}x_{1}, r_{3}x_{3} \\ r_{2}x_{2}, r_{4}x_{4} \end{bmatrix} \begin{bmatrix} r_{1}x_{1}, r_{2}x_{2} \\ r_{3}x_{3}, r_{4}x_{4} \end{bmatrix} = \begin{bmatrix} r_{1}x_{1} + r_{3}x_{3}, r_{2}x_{1} + r_{4}x_{3} \\ r_{1}x_{2} + r_{3}x_{4}, r_{4}x_{4} + r_{2}x_{2} \end{bmatrix}$$
(25)

We observe that the element on the diagonal are dependent, P(0) = p. Then

$$\mathbb{E}_{R}[(X \odot R)^{T}(X \odot R)] = \begin{bmatrix} pa_{1}^{2} + pa_{3}^{2}, 0\\ 0, pa_{2}^{2} + pa_{4}^{2} \end{bmatrix} = pX^{T}X$$
 (26)

Then we can go back to $\mathbb{E}_R[L(x)]$

$$\mathbb{E}_{R}[L(x)] = y^{T}y - 2py^{T}Xw + w^{T}E_{R}[(X \odot R)^{T}(X \odot R)]w + p^{2}w^{T}X^{T}Xw - p^{2}w^{T}X^{T}Xw$$
 (27)

$$= ||y - pXw||^2 - p^2 w^T X^T X w + w^T \mathbb{E}_R[(X \odot R)^T (X \odot R)] w$$
 (28)

$$= ||y - pXw||^2 + w^T \{ \mathbb{E}_R[(X \odot R)^T (X \odot R)] - p^2 X^T X \} w$$
 (29)

Where the term p^2X^TX in the $\{...\}$ part of the equation remove all the independent element previously seen. When the only have the diagonal left. $p(1-p)diag(X^TX)$

$$\mathbb{E}_{R}[L(x)] = ||y - pXw||^{2} + p(1-p)w^{T}diag(X^{T}X)w$$
(30)

$$= ||y - pXw||^2 + p(1-p)||\Gamma w||^2$$
(31)

4. I didn't found the solution for this one :(

Question 4 (5-5-5-5). (Paper Review: Vision Transformer)

In this question, you are going to write a **one page review** of the vision transformer paper. Please structure your review into the following sections:

(4.1) **Summary:**

- (a) What is this paper about?
- (b) What is the main contribution?
- (c) Describe the main approach and results. Just facts, no opinions yet.

(4.2) Strengths:

- (a) Is there a new theoretical insight?
- (b) Or a significant empirical advance? Did they solve a standing open problem?
- (c) Or a good formulation for a new problem?
- (d) Any good practical outcome (code, algorithm, etc)?
- (e) Are the experiments well executed?
- (f) Useful for the community in general?

(4.3) Weaknesses:

- (a) What can be done better?
- (b) Any missing baselines? Missing datasets?
- (c) Any odd design choices in the algorithm not explained well? Quality of writing?
- (d) Is there sufficient novelty in what they propose? Minor variation of previous work?
- (e) Why should anyone care? Is the problem interesting and significant?

(4.4) Reflections:

- (a) How does this relate to other concepts you have seen in the class?
- (b) What are the next research directions in this line of work?
- (c) What (directly or indirectly related) new ideas did this paper give you? What would you be curious to try?

Answer 4. Guillaume Thibault

4.1 Summary

The transformer is the primary architecture used for NLP and the authors' goal is to show that they can also be used for vision tasks without any CNN components. When trained with enough data, the vision transformer results can achieve the results of state-of-the-art convolutional neural networks with less computation required for training. They are also exploring the benefits of pre-training the models and then refining them on a specific task.

The standard Transformer receives as input a 1D sequence of token embeddings. To be able to use images, they add to divide the images into patches of fixed size. Then they linearly embed each one, added position embedding and passed the resulting vector sequence to a standard Transformer encoder. To perform classification, they use the standard approach of adding an additional learnable "classification token" to the sequence using an MLP. The author tried different model sizes, adding more and more layers to get a larger model. To train these models, they used the ImageNet ILSVRC-2012 dataset with 1k classes and 1.3M images, its ImageNet-21k superset with 21k classes and 14M images, and JFT with 18k classes and 303M high resolution images. Then, to perform their tests, they transferred the models trained on these datasets to several benchmark tasks.

4.3 Weaknesses

They found that ViT has much less image-specific inductive bias than CNNs and also performs better. The fact that they tested their models on multiple datasets makes them more reliable but one of these datasets, the largest, is private, so not all results are reproducible. They also claim that their model requires far fewer computational resources for pre-training, but training takes days in very expensive, not everyone can do the training. But they also tested it on the smaller, public ImageNet-21k dataset, and their results were good, making them more convincing about the results with the private dataset.

4.2 Strengths

They also analyze its internal representations. They showed that some attention heads attend to most of the image already in the lowest layers, showing that the global information integration capacity is used by the model. Other attentional heads consistently have small attentional distances in the lower layers, suggesting that they may have a similar function as the first convolution layers in CNNs. Finally, attentional distance increases with network depth. Overall, they find that the model focuses on regions of the image that are semantically relevant for classification.

4.4 Reflection

This article shows how to integrate image-related tasks with state-of-the-art NLP tasks. Knowing this, it could be interesting to merge the two and try to merge images and text to finds its semantics. Another area of research could be to try image segmentation with the model as we can see that the attention mechanism is quite good for object recognition.
